Cortical EEG slowing in resting-state Parkinson's disease

Final presentation: model, code, and findings

PD EEG group · Rui, Jan, Melissa, Friedrich · 26.06.2026

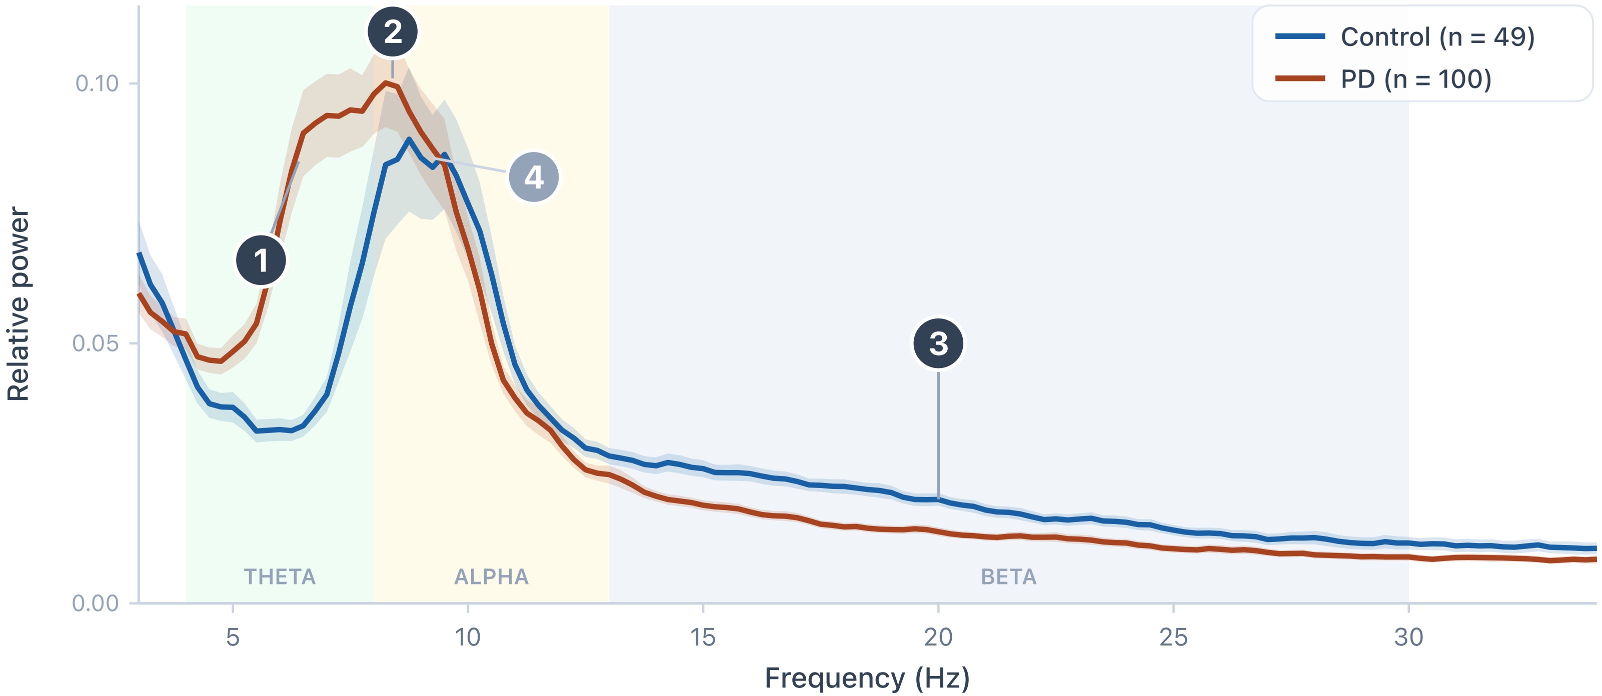
Hypotheses

① theta power higher
in PD · $p < 0.001$

② alpha peak slows
9.25 → 8.00 Hz · $p < 0.001$

③ beta power lower
in PD · $p < 0.001$

④ alpha power
unchanged · $p = 0.9$

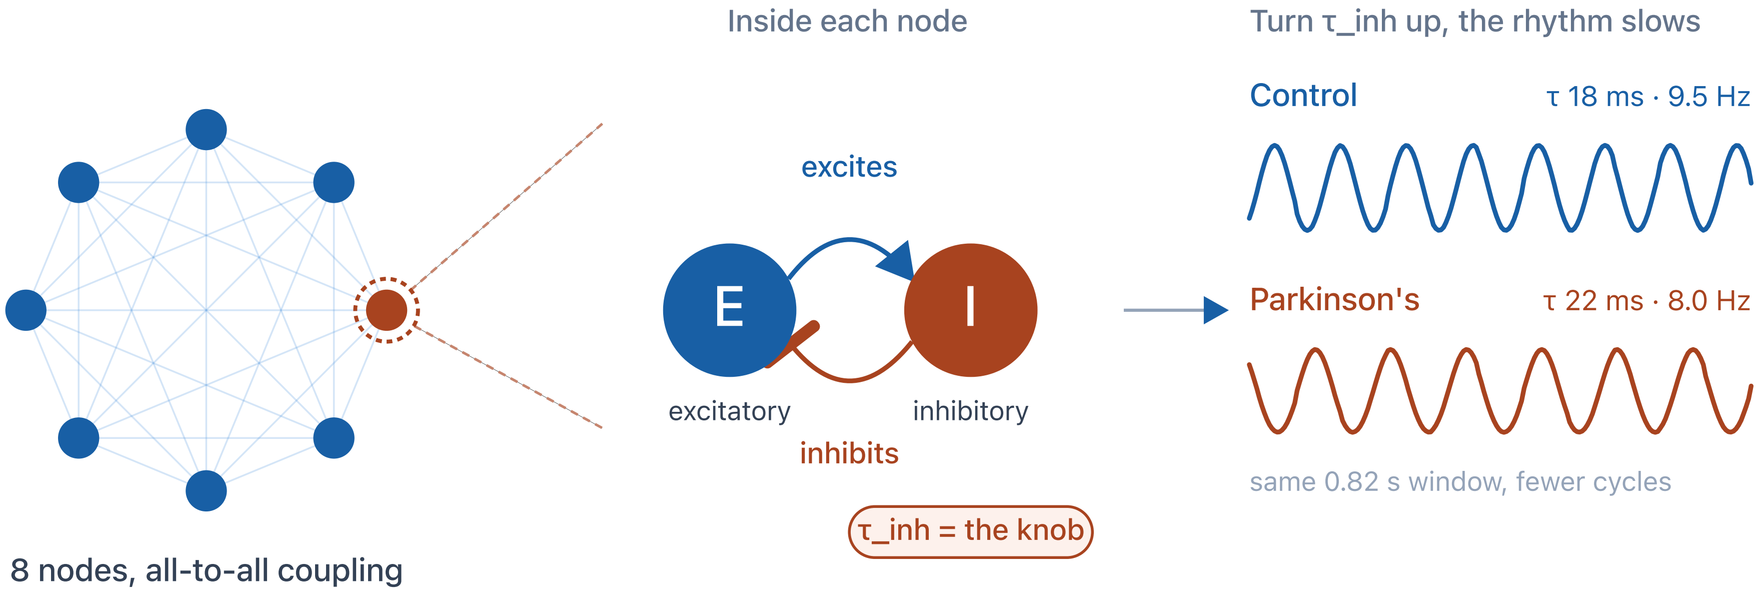


Three changes confirmed, one prediction null: the slowing is in frequency, not amplitude.

49 Control, 100 PD · posterior channels · relative power ±SEM · Mann-Whitney U

The model: a Wilson-Cowan network

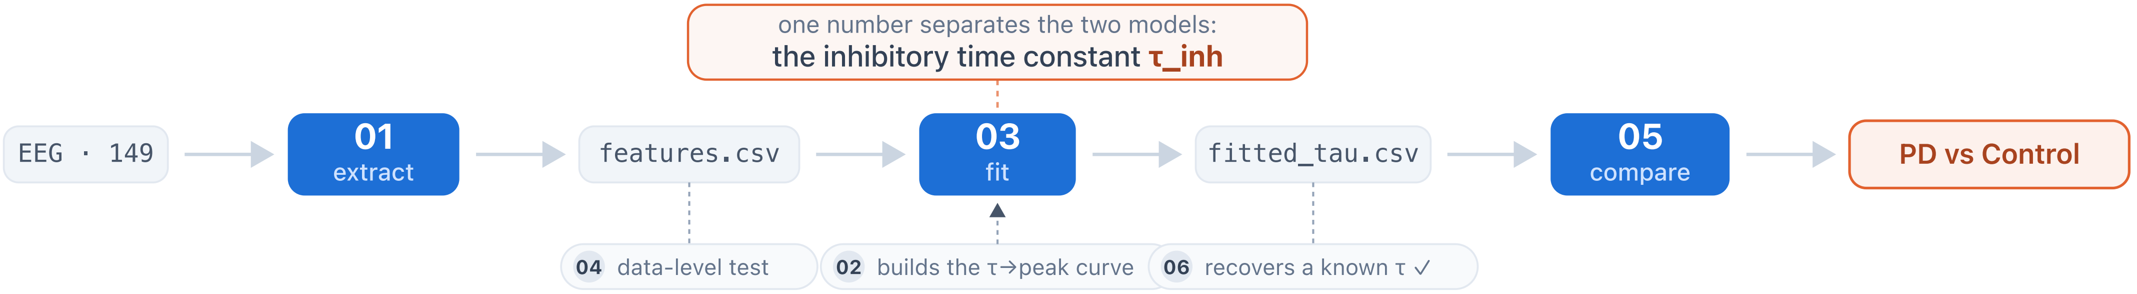
8 coupled cortical nodes, each an excitatory-inhibitory loop. τ_inh is the only knob we turn.



The final adaptation from healthy to patient is a single parameter: a longer inhibitory time constant **τ_inh**, about **+3.25 ms** in PD.

Code & repository

THE PIPELINE EEG to result, through six numbered scripts



THE REPOSITORY

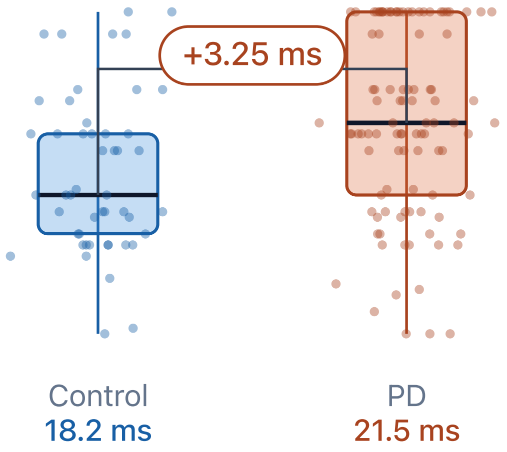
Does the model separate patients from controls?

Fitted inhibitory time constant

the model parameter we change for a patient

fitting recovers tau to ±0.5 ms, far below this group gap



Validation: recovering a known parameter

simulate at a known tau, fit it back

Fitted **τ_inh** is **+3.25 ms** higher in PD (one-sided Mann-Whitney, $p \approx 0.0002$). The recovery test shows this is a real separation, not an artefact of the fitting.

Outlook and open challenges

CURRENT CHALLENGES

- One parameter (τ_{inh}) reproduces the alpha slowing, but not the theta and beta changes
- The fit re-expresses the data-level effect, rather than adding independent evidence

FUTURE DIRECTIONS

- Fit more than the peak (full spectrum or functional connectivity), on a real connectome
- Relate fitted τ to clinical scores and to known inhibitory (GABAergic) changes in PD
