

Cortical EEG slowing in resting-state Parkinson's disease

Final presentation: model, code, and findings

PD EEG group · Rui, Jan, Melissa, Friedrich · 26.06.2026

Hypotheses

① theta power higher
in PD · $p < 0.001$

② alpha peak slows
9.25 → 8.00 Hz · $p < 0.001$

③ beta power lower
in PD · $p < 0.001$

④ alpha power
unchanged · $p = 0.9$

Three changes confirmed, one prediction null: the slowing is in frequency, not amplitude.

The model: a Wilson-Cowan network

THE MODEL: AN E-I LOOP

TURN τ_{inh} UP, THE RHYTHM SLOWS

each point = the model run at one knob setting

THE SIMULATED RHYTHM

The whole change from healthy to patient is one number: a longer inhibitory time constant τ_{inh} , about **+3.25 ms** in PD.

Code & repository

THE PIPELINE EEG to result, through six numbered scripts

THE REPOSITORY

every result is one script run

```
bash
$ python scripts/05_compare_tau.py
Control 18.25 → PD 21.50 ms diff +3.25 p = 0.00025 ***
→ wrote results/figures/compare_tau.png
$ python scripts/06_recover_tau.py
22 known tau recovered bias -0.10 max err 1.75 ms
→ wrote results/tau_recovery.csv
```

VERSION CONTROL

Does the model separate patients from controls?

Fitted inhibitory time constant

the model parameter we change for a patient

fitting recovers tau to ± 0.5 ms, far below this group gap

Validation: recovering a known parameter

simulate at a known tau, fit it back

Fitted τ_{inh} is **+3.25 ms** higher in PD (one-sided Mann-Whitney, $p \approx 0.0002$). The recovery test shows this is a real separation, not an artefact of the fitting.

Outlook and open challenges

CURRENT CHALLENGES

- One parameter (τ_{inh}) reproduces the alpha slowing, but not the theta and beta changes
- The fit re-expresses the data-level effect, rather than adding independent evidence

FUTURE DIRECTIONS

- Fit more than the peak (full spectrum or functional connectivity), on a real connectome
- Relate fitted τ to clinical scores and to known inhibitory (GABAergic) changes in PD
